# COPPER-CATALYZED FORMATION OF CARBON-HETEROATOM AND CARBON-CARBON BONDS

## *Background of the Invention*

5 N-Aryl amines and amides are important substructures in natural products and industrial chemicals, such as pharmaceuticals, dyes, and agricultural products. Palladium-catalyzed methods for the N-arylation of amines and amides are now widely-exploited for the synthesis of arylamine and N-arylamide moieties in pharmaceuticals, materials with important electronic properties, and ligands for early metal catalysts. Likewise, the  
10 palladium-catalyzed coupling to form carbon-carbon bonds between an aryl or vinyl halide and a carbon nucleophile is widely used. See, e.g., Stille, J. K. *Angew. Chem., Int. Ed. Engl.*, 25:508-524 (1986); Miyaura, N. et al., *Chem. Rev.*, 95:2457-2483 (1995); Negishi, E. *Acc. Chem. Res.*, 15:340-348 (1982).

However, the ever-increasing cost of palladium detracts from the allure of these  
15 powerful methods. Consequently, a need exists for a general and efficient catalytic method for synthesizing N-aryl amines and amides, from aryl halides and the corresponding amines and amides, based on a catalyst that does not comprise a rare, costly transition metal, such as palladium. Likewise, a need also exists for a general and efficient catalytic method for forming carbon-carbon bonds between an aryl or vinyl halide and a carbon nucleophile,  
20 based on a catalyst that does not comprise a rare, costly transition metal, such as palladium.

In 1998, bulk palladium sold on the international metal market for roughly five-thousand-times the cost of bulk copper. Therefore, based on catalyst cost, the aforementioned transformations would be orders of magnitude more appealing if they could be achieved with catalysts comprising copper in place of palladium.

#### *Cu-Catalyzed N-Arylation of Amides*

The coupling of aryl iodides and bromides with amides, the so-called Goldberg reaction, is not very general in terms of substrate scope, often requiring stoichiometric quantities of copper complexes. Moreover, as with the related Ullmann reaction, the reaction conditions for the Goldberg reaction are often quite harsh, with required temperatures as high as 210 °C. Nevertheless, the methods of the present invention effect these reactions using only 1 mol% CuI and have successfully used as little as 0.2 mol% CuI. In many instances, a system derived from 1% CuI, 10% (racemic)-*trans*-cyclohexane-1,2-diamine, and K<sub>3</sub>PO<sub>4</sub> or Cs<sub>2</sub>CO<sub>3</sub> provides an outstanding catalyst for the amidation of aryl iodides. Importantly, CuI is an air-stable Cu(I) source. As can be seen in the Exemplification, the process enjoys broad substrate scope with respect to the aryl iodide component. Notably, the arylation of a 2° amide-containing substrate and of 4-iodoaniline are possible; Pd-catalyzed C-N bond-forming processes with substrates that contain these

functional groups are not successful. We have also been able to N-arylate N-BOC hydrazine. Further, this process provides a convenient entry into the synthesis of hydrazines, and, therefore, a means to access Fischer indole substrates and other heterocycle synthons.

The copper-catalyzed methods of the present invention allow the amidation of aryl bromides. These reactions typically use 1-20 mol% CuI; for example, in one embodiment, 1 mol% CuI was used, yielding the product in 90% yield. Additionally, the coupling of an unactivated aryl chloride with an amide has also been achieved using the methods of the present invention.

The methods of the present invention also work well for the coupling of aryl iodides with primary amides; in fact, there appear to be no limitations on the nature of the acyl substituent (R in  $RC(O)NH_2$ ). With respect to 2° amides, N-acyl anilines and lactams are preferred substrates. N-formyl amides derived from alkyl amines are satisfactory substrates. Consequently, we believe that steric hindrance influences the outcome of the methods. In embodiments wherein ligand arylation competes with substrate arylation, the use of a 1,10-phenanthroline or an N,N'-dimethyl-1,2-diamine gives improved results.

In preferred embodiments, the  $pK_a$  of the amide is in the particular range of 20-25, as measured in DMSO. Generally, strong bases are less effective than weak bases in the methods of the present invention; for example,  $Cs_2CO_3$  and  $K_3PO_4$  are efficient bases in

many embodiments. For the coupling of aryl bromides at low catalyst loadings, and for the coupling of aryl chlorides, the use of  $K_2CO_3$  is preferred. These results are consistent with the notion that it is important to keep the concentration of the deprotonated amide low in order to prevent deactivation of the catalyst. Interestingly, to a certain extent, decreasing the catalyst loading does not appear to compromise the reaction efficiency.

#### *Cu-Catalyzed N-Arylation of Heterocycles*

In terms of the desirability of the products, some of the most important substrates for the catalyzed N-arylation are nitrogen-containing heterocycles, e.g., pyrrole, and indole. Previous reports of copper-mediated heterocycle N-arylations suffer from limitations similar to those of the Ullmann reaction. Likewise, the Cu-promoted or catalyzed coupling of heterocycles with aryl boronic acids is of limited scope. Moreover, boronic acids are much less attractive as precursors than aryl halides. Accordingly, a general solution to the arylation of heterocycles has been sought for years.

The methods of the present invention allow N-arylation of nitrogen-containing heteroaromatics using 2-haloanisole or 2-methyl indole as one of the coupling partners; in these embodiments, the methods of the present invention afford the desired products nearly quantitatively, whereas the same transformations are very difficult using Pd catalysts. Further, the methods of the present invention enable N-arylation of pyrazole and indazole. Accordingly, the methods of the present invention enable the arylation of a variety of nitrogen heterocycles.

Mild, inexpensive bases, such as  $K_3PO_4$  and  $K_2CO_3$ , are effective in these transformations. These reactions are usually very clean, and arene reduction is typically less

problematic than in corresponding Pd systems. The methods of the present invention are often able to effect the desired coupling with as little as 1 mol% CuI; however, elevated temperatures, e.g., 110 °C, are normally required for the reaction. Nevertheless, in certain embodiments, a method of the present invention provides an N-aryl heteroaromatic in good yield when performed at room temperature.

#### Definitions

For convenience, certain terms employed in the specification, examples, and appended claims are collected here.

The term "nucleophile" is recognized in the art, and as used herein means a chemical moiety having a reactive pair of electrons. Examples of nucleophiles include uncharged compounds such as water, amines, mercaptans and alcohols, and charged moieties such as alkoxides, thiolates, carbanions, and a variety of organic and inorganic anions. Illustrative anionic nucleophiles include simple anions such as hydroxide, azide, cyanide, thiocyanate, acetate, formate or chloroformate, and bisulfite. Organometallic reagents such as organocuprates, organozincs, organolithiums, Grignard reagents, enolates, acetylides, and the like may, under appropriate reaction conditions, be suitable nucleophiles. Hydride may also be a suitable nucleophile when reduction of the substrate is desired.

The term "electrophile" is art-recognized and refers to chemical moieties which can accept a pair of electrons from a nucleophile as defined above. Electrophiles useful in the method of the present invention include cyclic compounds such as epoxides, aziridines, episulfides, cyclic sulfates, carbonates, lactones, lactams and the like. Non-cyclic electrophiles include sulfates, sulfonates (e.g. tosylates), chlorides, bromides, iodides, and the like

The terms "electrophilic atom", "electrophilic center" and "reactive center" as used herein refer to the atom of the substrate which is attacked by, and forms a new bond to, the nucleophile. In most (but not all) cases, this will also be the atom from which the leaving group departs.

The term "electron-withdrawing group" is recognized in the art and as used herein means a functionality which draws electrons to itself more than a hydrogen atom would at the same position. Exemplary electron-withdrawing groups include nitro, ketone, aldehyde, sulfonyl, trifluoromethyl, -CN, chloride, and the like. The term "electron-donating group", as used herein, means a functionality which draws electrons to itself less than a hydrogen

atom would at the same position. Exemplary electron-donating groups include amino, methoxy, and the like.

The terms "Lewis base" and "Lewis basic" are recognized in the art, and refer to a chemical moiety capable of donating a pair of electrons under certain reaction conditions.

- 5 Examples of Lewis basic moieties include uncharged compounds such as alcohols, thiols, olefins, and amines, and charged moieties such as alkoxides, thiolates, carbanions, and a variety of other organic anions.

The term "Bronsted base" is art-recognized and refers to an uncharged or charged atom or molecule, e.g., an oxide, amine, alkoxide, or carbonate, that is a proton acceptor.

- 10 The terms "Lewis acid" and "Lewis acidic" are art-recognized and refer to chemical moieties which can accept a pair of electrons from a Lewis base.

The term "meso compound" is recognized in the art and means a chemical compound which has at least two chiral centers but is achiral due to an internal plane, or point, of symmetry.

- 15 The term "chiral" refers to molecules which have the property of non-superimposability on their mirror image partner, while the term "achiral" refers to molecules which are superimposable on their mirror image partner. A "prochiral molecule" is an achiral molecule which has the potential to be converted to a chiral molecule in a particular process.

- 20 The term "stereoisomers" refers to compounds which have identical chemical constitution, but differ with regard to the arrangement of their atoms or groups in space. In particular, the term "enantiomers" refers to two stereoisomers of a compound which are non-superimposable mirror images of one another. The term "diastereomers", on the other hand, refers to the relationship between a pair of stereoisomers that comprise two or more  
25 asymmetric centers and are not mirror images of one another.

- Furthermore, a "stereoselective process" is one which produces a particular stereoisomer of a reaction product in preference to other possible stereoisomers of that product. An "enantioselective process" is one which favors production of one of the two possible enantiomers of a reaction product. The subject method is said to produce a  
30 "stereoselectively-enriched" product (e.g., enantioselectively-enriched or diastereoselectively-enriched) when the yield of a particular stereoisomer of the product is greater by a statistically significant amount relative to the yield of that stereoisomer

resulting from the same reaction run in the absence of a chiral catalyst. For example, an enantioselective reaction catalyzed by one of the subject chiral catalysts will yield an e.e. for a particular enantiomer that is larger than the e.e. of the reaction lacking the chiral catalyst.

The term "regioisomers" refers to compounds which have the same molecular  
5 formula but differ in the connectivity of the atoms. Accordingly, a "regioselective process" is one which favors the production of a particular regioisomer over others, e.g., the reaction produces a statistically significant preponderance of a certain regioisomer.

The term "reaction product" means a compound which results from the reaction of a nucleophile and a substrate. In general, the term "reaction product" will be used herein to  
10 refer to a stable, isolable compound, and not to unstable intermediates or transition states.

The term "substrate" is intended to mean a chemical compound which can react with a nucleophile, or with a ring-expansion reagent, according to the present invention, to yield at least one product having a stereogenic center.

The term "catalytic amount" is recognized in the art and means a substoichiometric  
15 amount relative to a reactant.

As discussed more fully below, the reactions contemplated in the present invention include reactions which are enantioselective, diastereoselective, and/or regioselective. An enantioselective reaction is a reaction which converts an achiral reactant to a chiral product enriched in one enantiomer. Enantioselectivity is generally quantified as "enantiomeric  
20 excess" (ee) defined as follows:

$$\% \text{ Enantiomeric Excess A (ee)} = (\% \text{ Enantiomer A}) - (\% \text{ Enantiomer B})$$

where A and B are the enantiomers formed. Additional terms that are used in conjunction with enantioselectivity include "optical purity" or "optical activity". An enantioselective reaction yields a product with an e.e. greater than zero. Preferred enantioselective reactions  
25 yield a product with an e.e. greater than 20%, more preferably greater than 50%, even more preferably greater than 70%, and most preferably greater than 80%.

A diastereoselective reaction converts a chiral reactant (which may be racemic or enantiomerically pure) to a product enriched in one diastereomer. If the chiral reactant is racemic, in the presence of a chiral non-racemic reagent or catalyst, one reactant enantiomer  
30 may react more slowly than the other. This class of reaction is termed a kinetic resolution, wherein the reactant enantiomers are resolved by differential reaction rate to yield both enantiomerically-enriched product and enantimerically-enriched unreacted substrate.

Kinetic resolution is usually achieved by the use of sufficient reagent to react with only one reactant enantiomer (i.e. one-half mole of reagent per mole of racemic substrate). Examples of catalytic reactions which have been used for kinetic resolution of racemic reactants include the Sharpless epoxidation and the Noyori hydrogenation.

- 5           A regioselective reaction is a reaction which occurs preferentially at one reactive center rather than another non-identical reactive center. For example, a regioselective reaction of an unsymmetrically substituted epoxide substrate would involve preferential reaction at one of the two epoxide ring carbons.

          The term "non-racemic" with respect to the chiral catalyst, means a preparation of  
10 catalyst having greater than 50% of a given enantiomer, more preferably at least 75%. "Substantially non-racemic" refers to preparations of the catalyst which have greater than 90% ee for a given enantiomer of the catalyst, more preferably greater than 95% ee.

          The term "alkyl" refers to the radical of saturated aliphatic groups, including straight-chain alkyl groups, branched-chain alkyl groups, cycloalkyl (alicyclic) groups, alkyl  
15 substituted cycloalkyl groups, and cycloalkyl substituted alkyl groups. In preferred embodiments, a straight chain or branched chain alkyl has 30 or fewer carbon atoms in its backbone (e.g., C<sub>1</sub>-C<sub>30</sub> for straight chain, C<sub>3</sub>-C<sub>30</sub> for branched chain), and more preferably 20 or fewer. Likewise, preferred cycloalkyls have from 4-10 carbon atoms in their ring structure, and more preferably have 5, 6 or 7 carbons in the ring structure.

20           Unless the number of carbons is otherwise specified, "lower alkyl" as used herein means an alkyl group, as defined above, but having from one to ten carbons, more preferably from one to six carbon atoms in its backbone structure. Likewise, "lower alkenyl" and "lower alkynyl" have similar chain lengths.

          The terms "alkenyl" and "alkynyl" refer to unsaturated aliphatic groups analogous in  
25 length and possible substitution to the alkyls described above, but which contain at least one double or triple carbon-carbon bond, respectively.

30 and phenyl-trimethyl-tin.

- 5 Where X is an oxygen and R<sub>11</sub> or R'<sub>11</sub> is not hydrogen, the formula represents an "ester". Where X is an oxygen, and R<sub>11</sub> is as defined above, the moiety is referred to herein as a carboxyl group, and particularly when R<sub>11</sub> is a hydrogen, the formula represents a "carboxylic acid". #### Catalysts of the Invention

10 In general, the catalysts used in the methods of the present invention comprise a copper atom or ion, and a ligand. The copper atom or ion of the catalyst may be derived from any commercially available copper salt, e.g., a copper (I) or copper (II) salt. In certain embodiments, the copper atom or ion is provided as copper (I) iodide.

The ligand of a catalyst comprises a Lewis basic atom, e.g., selected from nitrogen, oxygen, sulfur, phosphorus, and arsenic, such that the Lewis basic atom is capable of interacting with the aforementioned copper atom or ion. The ligand of a catalyst may be a chelating ligand, i.e., a ligand comprising two Lewis basic atoms, e.g., selected from nitrogen, oxygen, phosphorus, and arsenic, with a spatial relationship therebetween, such that the Lewis basic atoms are capable of interacting simultaneously with the  
15 aforementioned copper atom or ion. For example, a chelating ligand may be a diamine, aminoalcohol, or a bis-phosphine. In certain embodiments, a chelating ligand is a 1,2-diamine, or 1,3-diamine. In certain embodiments, a chelating ligand is a 1,2-diaminocyclohexane, a 1,10-phenanthroline, a 2-hydroxyethyl amine, or a 1,2-diaminoethane. In certain embodiments, a chelating ligand is 1,2-diaminocyclohexane,  
20 N,N'-dimethyl-1,2-diaminocyclohexane, N-tolyl-1,2-diaminocyclohexane, 1,10-phenanthroline, ethanolamine, 1,2-diaminoethane, or N,N'-dimethyl-1,2-diaminoethane. In certain embodiments, a chelating ligand is cis-1,2-diaminocyclohexane, trans-1,2-diaminocyclohexane, or a mixture of cis- and trans-1,2-diaminocyclohexane. Additionally, with respect to asymmetric chelating ligands, the ligand may be provided as a single  
25 enantiomer, a mixture of stereoisomers, or a racemic mixture. In certain embodiments, the ligand serves as the solvent for a method of the present invention. For example, in an embodiment wherein the ligand comprised by the catalyst is an amine that is a liquid under  
30

the conditions for practicing a method of the present invention, the method may be practiced using said amine as the solvent.

The copper atom or ion and the ligand of the catalyst of the methods of the present invention may be added to the reaction mixture separately or simultaneously, or they may be added in the form of preformed catalyst complex. Although the methods of the present invention do not require the formation of a copper-chelating ligand complex, such complexes are likely present. Moreover, the identity of the ligand effects various characteristics of the methods of the present invention.

In certain embodiments, the catalyst of a method of the present invention is covalently tethered to a solid support, e.g., a polymer bead or a resin. For example, the ligand of a catalyst of the present invention may be covalently tethered to a solid support, e.g., a Wang resin. Additionally, one or more of the substrates of a method of the present invention may be covalently tethered to a solid support, e.g., a polymer bead or a resin. For example, the Z-X substrate of a method of the present invention may be covalently tethered to a solid support, e.g., a Wang resin. Alternatively, the nucleophilic substrate, i.e., the substrate that effectively replaces X in Z-X, of a method of the present invention may be covalently tethered to a solid support, e.g., a Wang resin. Further, in certain embodiments, both substrates may be covalently tethered to a solid support. In certain embodiments, one or more of the substrates or the catalyst or any of them are isolated in a semi-permeable membrane, e.g., a dialysis bag.

#### Suitable Bases

A wide range of Bronsted bases may be used in the methods of the present invention. Generally, any Bronsted base may be used in the methods of the present invention. For example, suitable bases include  $K_3PO_4$ ,  $K_2CO_3$ ,  $Na_2CO_3$ ,  $Tl_2CO_3$ ,  $Cs_2CO_3$ ,  $K(OtBu)$ ,  $Li(OtBu)$ ,  $Na(OtBu)$ ,  $K(OPh)$ , and  $Na(OPh)$ , or mixtures thereof. In certain embodiments, the Bronsted base used will be selected from the group consisting of phosphates, carbonates, and alkoxides. In certain embodiments, the base is selected from the group consisting of potassium phosphate, potassium carbonate, cesium carbonate, and sodium *tert*-butoxide.

Typically, there is no need to use large excesses of base in the methods of the present invention. In certain embodiments, no more than four equivalents of base are used, relative to the nucleophilic reactant. In other embodiments, no more than two equivalents

of base are used, relative to the nucleophilic reactant. Further, in reactions using the corresponding anion of the nucleophilic reactant in place of its conjugate base, there may be no need for additional base.

### Nucleophiles

5 Nucleophiles which are useful in the methods of the present invention may be selected by the skilled artisan according to several criteria. In general, a suitable nucleophile will have one or more of the following properties: 1) It will be capable of reaction with the substrate at the desired electrophilic site; 2) It will yield a useful product upon reaction with the substrate; 3) It will not react with the substrate at functionalities  
10 other than the desired electrophilic site; 4) It will react with the substrate at least partly through a mechanism catalyzed by the chiral catalyst; 5) It will not substantially undergo further undesired reaction after reacting with the substrate in the desired sense; and 6) It will not substantially react with or degrade the catalyst. It will be understood that while undesirable side reactions (such as catalyst degradation) may occur, the rates of such  
15 reactions can be rendered slow -- through the selection of reactants and conditions -- in comparison with the rate of the desired reaction(s).

Routine experimentation may be necessary to determine the preferred nucleophile for a given transformation. For example, if a nitrogen-containing nucleophile is desired, in order to form a carbon-nitrogen bond, it may be selected from the group comprising amines,  
20 amides, and imides. Further, heteroaromatics may also be used as the nucleophilic reactant. For example, a carbon-nitrogen bond may be formed comprising the nitrogen of an optionally substituted indole, pyrrole, or carbazole. Moreover, numerous other nitrogen-containing functional groups serve as substrates in the instant methods of forming carbon-nitrogen bonds. For example, hydrazines, acylhydrazines, hydrazones, imines, and  
25 alkoxycarbonylhydrazines are suitable substrates for the carbon-nitrogen bond-forming methods of the present invention.

Similarly, an oxygen-containing nucleophile, such as an alcohol, alkoxide, or siloxane, may be used to form an oxygen-carbon bond; and a sulfur-containing nucleophile, such as a mercaptan, may be used to form a carbon-sulfur bond. Likewise, a carbon  
30 nucleophile, e.g., a malonate or a beta-keto ester, may be used to form a carbon-carbon bond. Additional suitable nucleophiles will be apparent to those of ordinary skill in the art of organic chemistry. A nucleophile introduced in the reaction mixture as an anion may

comprise a conventional counterion, e.g., an alkali metal cation, alkaline earth cation, or ammonium ion. In certain embodiments, the nucleophilic moiety may be part of the substrate, resulting in an intramolecular bond-forming reaction.

In certain embodiments, the nucleophile is selected from the group consisting of  
5 primary amides, secondary amides, lactams, hydrazines, imines, hydrazones, carbazates, primary amines, secondary amines, NH-containing heteroaromatics (e.g., pyrroles, indoles, and imidazoles), malonates, carbamates, imides, and alcohols.

Aryl, Heteroaryl or Vinyl Halides or Sulfonates

The methods of the present invention may be used to form a bond between the  
10 halogen-bearing or sulfonate-bearing carbon atom of an aryl halide or sulfonate, heteroaryl halide or sulfonate, or vinyl halide or sulfonate, and a nucleophilic nitrogen or carbon or oxygen atom of a second molecule. Of course, as mentioned *supra*, the halogen-bearing carbon of the aryl halide, heteroaryl halide, or vinyl halide, or the sulfonate-bearing carbon of the aryl sulfonate, heteroaryl sulfonate, or vinyl sulfonate, and the nucleophilic nitrogen  
15 or carbon may be part of a single molecule, rendering the bond-formation intramolecular.

In certain embodiments, an aryl halide or sulfonate is used, wherein its aryl moiety is a radical of an aromatic hydrocarbon (single or polycyclic), such as benzene, naphthalene, anthracene and phenanthrene. In certain embodiments, the aryl halide may be selected from the group consisting of optionally-substituted phenyl halides.

20 In certain embodiments, a heteroaryl halide or sulfonate is used, wherein its heteroaryl moiety is a radical of an heteroaromatic (single or polycyclic), such as pyrrole, thiophene, thianthrene, furan, pyran, isobenzofuran, chromene, xanthene, phenoxathiin, pyrrole, imidazole, pyrazole, thiazole, isothiazole, isoxazole, pyridine, pyrazine, pyrimidine, pyridazine, indolizine, isoindole, indole, indazole, purine, quinolizine, isoquinoline,  
25 quinoline, phthalazine, naphthyridine, quinoxaline, quinazoline, cinnoline, pteridine, carbazole, carboline, phenanthridine, acridine, perimidine, phenanthroline, phenazine, phenarsazine, phenothiazine, furazan, phenoxazine, pyrrolidine, oxolane, thiolane, oxazole, piperidine, piperazine, morpholine.

In general, suitable aromatic compounds have the formula  $Z_p\text{ArX}$ , wherein Ar is  
30 aryl or heteroaryl; and X is a sulfonate or a halogen selected from the group consisting of chlorine, bromine, and iodine. In certain embodiments, X is a halide selected from the group consisting of chlorine, bromine, and iodine. In certain embodiments, X represents a

sulfonate moiety. Further, Z represents one or more optional substituents on the aromatic ring, though each occurrence of Z ( $p > 1$ ) is independently selected. By way of example only, each incidence of substitution independently can be, as valence and stability permit, a halogen, a lower alkyl, a lower alkenyl, a lower alkynyl, a carbonyl (e.g., an ester, a carboxylate, or a formate), a thiocarbonyl (e.g., a thiolester, a thiolcarboxylate, or a thiolformate), an aldehyde, an amino, an acylamino, an amido, an amidino, a cyano, a nitro, an azido, a sulfonyl, a sulfoxido, a sulfate, a sulfonate, a sulfamoyl, a sulfonamido, a phosphoryl, a phosphonate, a phosphinate,  $-(CH_2)_m-R_8$ ,  $-(CH_2)_m-OH$ ,  $-(CH_2)_m-O$ -lower alkyl,  $-(CH_2)_m-O$ -lower alkenyl,  $-(CH_2)_m-O-(CH_2)_n-R_8$ ,  $-(CH_2)_m-SH$ ,  $-(CH_2)_m-S$ -lower alkyl,  $-(CH_2)_m-S$ -lower alkenyl,  $-(CH_2)_m-S-(CH_2)_n-R_8$ , or protecting groups of the above or a solid or polymeric support;  $R_8$  represents a substituted or unsubstituted aryl, aralkyl, cycloalkyl, cycloalkenyl, or heterocycle; and n and m are independently for each occurrence zero or an integer in the range of 1 to 6. When the aryl moiety is phenyl, p is in the range of 0 to 5. For fused rings, where the number of potential substitution sites on the aryl moiety is greater than five, the range defined for p must be adjusted appropriately.

#### Reaction Conditions

The methods of the present invention may be performed under a wide range of conditions, though it will be understood that the solvents and temperature ranges recited herein are not limitative and only correspond to a preferred mode of the process of the invention.

In general, it will be desirable that reactions are run using mild conditions which will not adversely affect the reactants, the catalyst, or the product. For example, the reaction temperature influences the speed of the reaction, as well as the stability of the reactants, products and catalyst.

In certain embodiments, the methods of the present invention are conducted at a temperature less than about 150 C. In certain embodiments, the methods of the present invention are conducted at a temperature less than about 140 C. In certain embodiments, the methods of the present invention are conducted at a temperature less than about 110 C. In certain embodiments, the methods of the present invention are conducted at a temperature less than about 100 C. In certain embodiments, the methods of the present invention are conducted at a temperature less than about 90 C. In certain embodiments, the methods of the present invention are conducted at a temperature less than about 50 C. In

certain embodiments, the methods of the present invention are conducted at a temperature less than about 40 C. In certain embodiments, the methods of the present invention are conducted at ambient temperature.

In general, the subject reactions are carried out in a liquid reaction medium. The reactions may be run without addition of solvent. Alternatively, the reactions may be run in an inert solvent, preferably one in which the reaction ingredients, including the catalyst, are substantially soluble. Suitable solvents include ethers such as diethyl ether, 1,2-dimethoxyethane, diglyme, t-butyl methyl ether, tetrahydrofuran and the like; halogenated solvents such as chloroform, dichloromethane, dichloroethane, chlorobenzene, and the like; aliphatic or aromatic hydrocarbon solvents such as benzene, xylene, toluene, hexane, pentane and the like; esters and ketones such as ethyl acetate, acetone, and 2-butanone; polar aprotic solvents such as acetonitrile, dimethylsulfoxide, dimethylformamide and the like; or combinations of two or more solvents.

The invention also contemplates reaction in a biphasic mixture of solvents, in an emulsion or suspension, or reaction in a lipid vesicle or bilayer. In certain embodiments, it may be preferred to perform the catalyzed reactions in the solid phase with one of the reactants anchored to a solid support.

In certain embodiments it is preferable to perform the reactions under an inert atmosphere of a gas such as nitrogen or argon.

The reaction processes of the present invention can be conducted in continuous, semi-continuous or batch fashion and may involve a liquid recycle operation as desired. The processes of this invention are preferably conducted in batch fashion. Likewise, the manner or order of addition of the reaction ingredients, catalyst and solvent are also not generally critical to the success of the reaction, and may be accomplished in any conventional fashion.

The reaction can be conducted in a single reaction zone or in a plurality of reaction zones, in series or in parallel or it may be conducted batchwise or continuously in an elongated tubular zone or series of such zones. The materials of construction employed should be inert to the starting materials during the reaction and the fabrication of the equipment should be able to withstand the reaction temperatures and pressures. Means to introduce and/or adjust the quantity of starting materials or ingredients introduced batchwise or continuously into the reaction zone during the course of the reaction can be

conveniently utilized in the processes especially to maintain the desired molar ratio of the starting materials. The reaction steps may be effected by the incremental addition of one of the starting materials to the other. Also, the reaction steps can be combined by the joint addition of the starting materials to the metal catalyst. When complete conversion is not  
5 desired or not obtainable, the starting materials can be separated from the product and then recycled back into the reaction zone.

The processes may be conducted in either glass lined, stainless steel or similar type reaction equipment. The reaction zone may be fitted with one or more internal and/or external heat exchanger(s) in order to control undue temperature fluctuations, or to prevent  
10 any possible "runaway" reaction temperatures.

Furthermore, one or more of the reactants or the catalyst can be immobilized by attachment to or incorporation into a polymer or other insoluble matrix.

#### Subsequent Transformations

A product synthesized by a method of the present invention may be either an end-  
15 product or an intermediate in a synthesis scheme. In cases where the product synthesized by a method of the present invention is an intermediate, the product may be subjected to one or more additional transformations to yield the desired end-product. The set of additional transformations contemplated comprises isomerizations, hydrolyses, oxidations, reductions, additions, eliminations, olefinations, functional group interconversions, transition metal-  
20 mediated reactions, transition metal-catalyzed reactions, bond-forming reactions, cleavage reactions, fragmentation reactions, thermal reactions, photochemical reactions, cycloadditions, sigmatropic rearrangements, electrocyclic reactions, chemoselective reactions, regioselective reactions, stereoselective reactions, diastereoselective reactions, enantioselective reactions, and kinetic resolutions. The invention expressly comprises use  
25 of a method of the present invention as a step -- either initial, intermediate or final -- in the synthesis of known or new pharmaceuticals, e.g., antivirals, antibiotics, and analgesics.

#### Combinatorial Libraries

The subject methods of the present invention readily lend themselves to the creation of combinatorial libraries of compounds for the screening of pharmaceutical, agrochemical  
30 or other biological or medical activity or material-related qualities. A combinatorial library for the purposes of the present invention is a mixture of chemically related compounds which may be screened together for a desired property; said libraries may be in solution or

covalently linked to a solid support. The preparation of many related compounds in a single reaction greatly reduces and simplifies the number of screening processes which need to be carried out. Screening for the appropriate biological, pharmaceutical, agrochemical or physical property may be done by conventional methods.

5           Diversity in a library can be created at a variety of different levels. For instance, the substrate aryl groups used in a combinatorial approach can be diverse in terms of the core aryl moiety, e.g., a variegation in terms of the ring structure, and/or can be varied with respect to the other substituents.

          A variety of techniques are available in the art for generating combinatorial libraries of small organic molecules. See, for example, Blondelle et al. (1995) Trends Anal. Chem. 14:83; the Affymax U.S. Patents 5,359,115 and 5,362,899; the Ellman U.S. Patent 5,288,514; the Still et al. PCT publication WO 94/08051; Chen et al. (1994) JACS 116:2661; Kerr et al. (1993) JACS 115:252; PCT publications WO92/10092, WO93/09668 and WO91/07087; and the Lerner et al. PCT publication WO93/20242). Accordingly, a  
10           variety of libraries on the order of about 16 to 1,000,000 or more diversomers can be synthesized and screened for a particular activity or property.  
15

          In an exemplary embodiment, a library of substituted diversomers can be synthesized using the subject reactions adapted to the techniques described in the Still et al. PCT publication WO 94/08051, e.g., being linked to a polymer bead by a hydrolyzable or  
20           photolabile group, e.g., located at one of the positions of substrate. According to the Still et al. technique, the library is synthesized on a set of beads, each bead including a set of tags identifying the particular diversomer on that bead. In one embodiment, which is particularly suitable for discovering enzyme inhibitors, the beads can be dispersed on the surface of a permeable membrane, and the diversomers released from the beads by lysis of  
25           the bead linker. The diversomer from each bead will diffuse across the membrane to an assay zone, where it will interact with an enzyme assay.
